

## Heat Engines:

- Ideal:

Cold Reservoir  $T_C$

- $Q_H = W$
- This can never happen.

- Actual:

- $W = |Q_H| - |Q_C|$
- Thermal efficiency:  
$$e \equiv \frac{W}{|Q_H|} = \frac{|Q_H| - |Q_C|}{|Q_H|}$$
$$= 1 - \frac{|Q_C|}{|Q_H|}$$

An engine transfers  $2.00 \text{E}3 \text{ J}$  of energy from a hot reservoir during a cycle and transfers  $1.50 \text{E}3 \text{ J}$  as exhaust to a cold reservoir.

a) Find the efficiency of the engine.

b) How much work does this engine do in one cycle?

$$\begin{aligned} \text{a)} \quad e &= 1 - \frac{|Q_c|}{|Q_H|} \\ &= 1 - \frac{1.5 \text{E}3 \text{ J}}{2 \text{E}3 \text{ J}} \\ &= 0.25 \end{aligned}$$

$$\begin{aligned} \text{b)} \quad W &= |Q_H| - |Q_c| \\ &= 2 \text{E}3 \text{ J} - 1.5 \text{E}3 \text{ J} \\ &= 5 \text{E}2 \text{ J} \end{aligned}$$

## Reversible v. Irreversible:

- Reversible process is one in which the system may return to its initial conditions along the same path in a PV diagram.
- Irreversible process is one where equilibrium is not maintained throughout the process. This is the state of all real processes.

Ideal, reversible cycle: Carnot cycle

100% efficient

A  $\rightarrow$  B isothermal expansion of a gas

B  $\rightarrow$  C adiabatic expansion  
(no heat coming into system)

C  $\rightarrow$  D isothermal compression  
 $Q_C$  (heat leaving)

D  $\rightarrow$  A adiabatic compression
